Simple Linear Regression Examples, Problems, and Solutions.

Simple linear regression allows us to study the correlation between only two variables: One variable (X) is called independent variable or predictor. The other variable (Y), is known as dependent variable or outcome. and the simple linear regression equation is:  $Y = B_0 + B_1 X$ . Where:

The linear regression has the assumptions of normality, homoscedasticity, multicollinearity, and the absence of outliers. The assumption of normality can be assessed by plotting the quantiles of the model residuals against the quantiles of a Chi-square distribution, also called a Q-Q scatterplot.

Multicollinearity occurs when independent variables in a regression model are correlated. This correlation is a problem because independent variables should be independent. If the degree of correlation between variables is high enough, it can cause problems when you fit the model and interpret the results.
